

Institutional Forecasts vs. a Full-Account

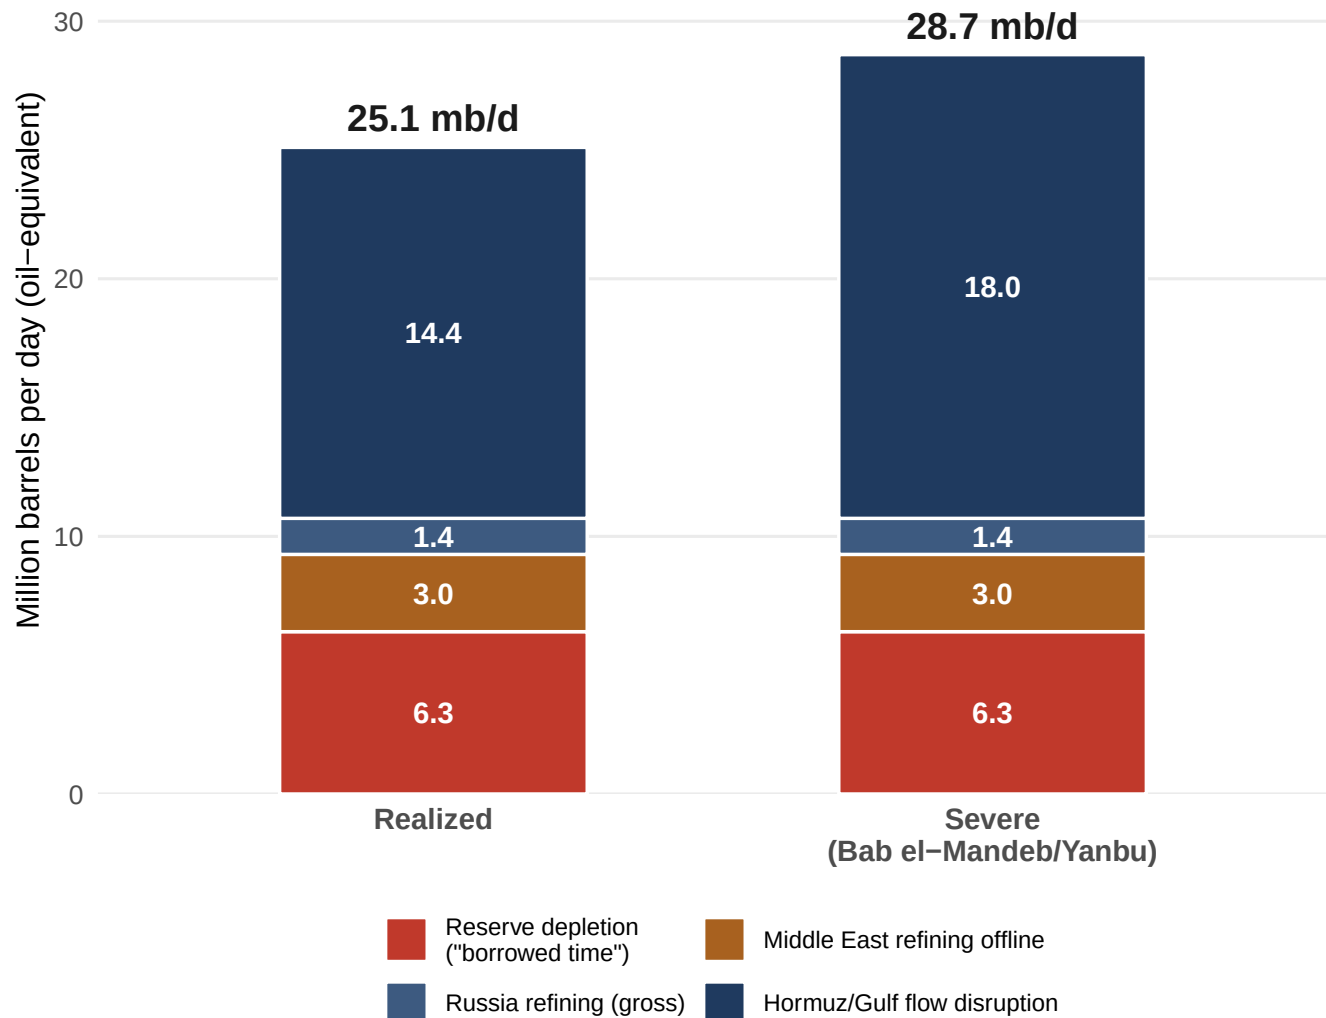

Estimated 2026 global GDP (GWP) impact — flow disruption

Estimates apply an energy-to-GDP conversion factor (0.79) to the full measure of Russian refining capacity lost + a global reserve-depletion rate (ex-Gulf, oil-oil-oil). Institutional comparators: IMF World Economic Outlook (Apr 2026); Oxford Economics (Apr 2026).

What's Driving the Disruption: Four Components, Not One

Million barrels/day (oil-equivalent), by contributing factor

Reserve depletion represents borrowed time, not a permanent loss -- it's the rate at which stocks are being spent to mask the shortfall, which converts into unmasked shortfall once reserves run out.
